FREIGHT ACCESSIBILITY AND ECONOMIC DEVELOPMENT

Case Studies in Practical Measurement

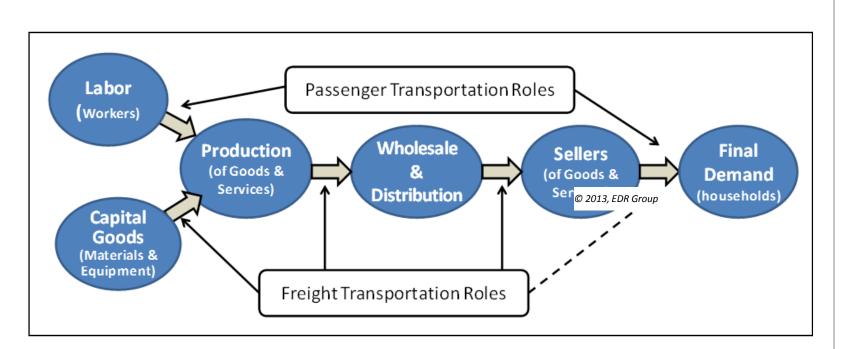

Accessibility is "the *potential* of opportunities for interaction." (Walter Hansen, 1959)

A lack of freight accessibility limits economic development and growth.

Naomi Stein, Glen Weisbrod, Adam Blair

→ Why Freight Access?

TRANSPORTATION & THE ECONOMY

Sources of Access Issues: Geometric constraints. Service provision and scheduling constraints. Volume-to-capacity constraints. Circuity, network coverage, and remoteness.

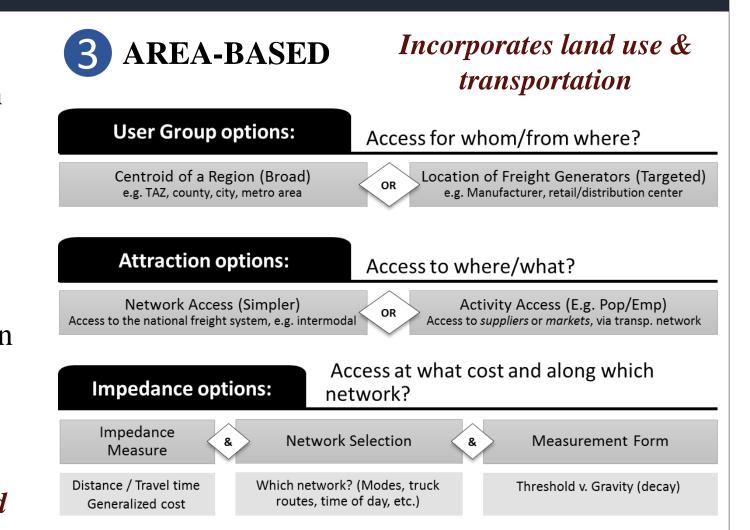

Types of Metrics

- 1 INFRASTRUCTURE-BASED
 - "Traditional" Performance on a link/corridor/node
 - E.g. Speed, transfer time, V/C, Travel Time Index

2 NETWORK MEASURES

- Coverage / completeness within a specified geography
- E.g. intersections of miles of network w/in a X mile radius

No direct measurement of land-use and activity distributions in geographic space

Analysis Process

Step 1: Define Local & Regional Context
Step 2: Identify Freight Access Needs & Issues
Step 3: Select Measurement Approach
Step 4: Measure & Interpret

Insights
Where is access most constrained?

How much better could it be?

Compare by mode between areas

Compare...by mode | ...between areas | ...between congested & uncongested | ...over time / different scenarios | ...with or without a project

Performance measurement

Tracking/Forecasting

Criteria for investment decision-making

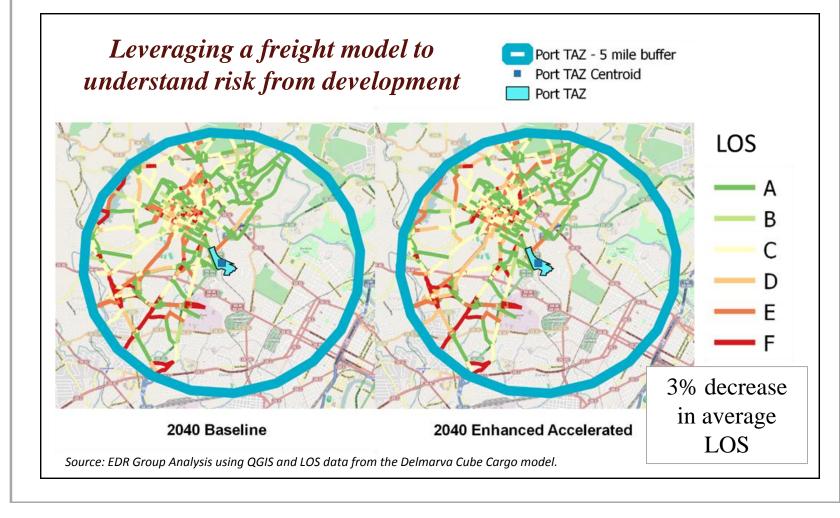

Illustrative Case Studies: Application of Freight Access Metrics

Port of Wilmington (Delaware)

- Context: urban setting; adjacent to two interstates; access via local street network; supports energy, food, and transportation equipment supply chains.
- Accessibility Issues: Existing truck queuing, pressure on local roads during peak; anticipated pressures from industrial development and growth in port activity.
- Measurement: Compare across alternative futures

 **Infrastructure based: LOS on key facilities

 **Area-based: employment accessible from the port

Appalachian Region

- Context: 13 states, 25 million people, largely rural/isolated, transitioning from extractive industries, agriculture, and heavy manufacturing to services & specialized manufacturing.
- Accessibility Issues: Originally bypassed by Interstate system, inadequate access to ports/intermodal facilities for international trade.
- Measurement: Multimodal network access indicators applied comparatively across counties. Multi-criteria weighting based on stakeholder priorities.

Selection of relatively simple measures to enable consistent analysis across a large region

From County Centroid to:

Interstate highway (entry/exit ramps)
ADHS/national highway (links)
Intermodal (Container) Rail Terminals
Multimodal Rail Terminals (noncontainer terminals)
Inland Waterway Port
Intermodal-Interstate Intersection
Coastal Ports

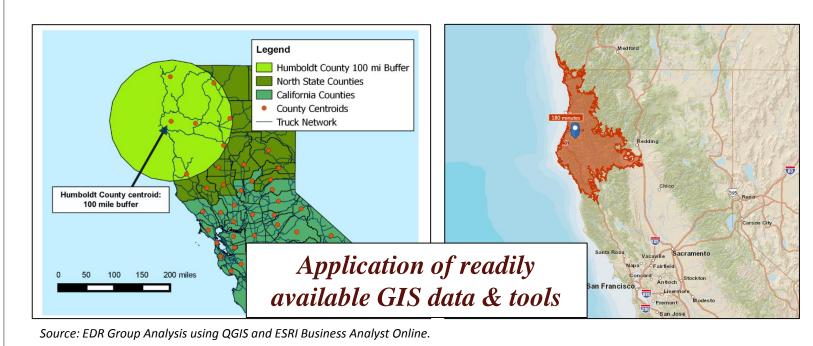

North State Super Region of California

- Context:16-county region characterized by mostly rural coastal areas, mountains, and agriculture; Unemployment and poverty rates are higher than CA average.
- Accessibility Issues: Remoteness, poor connectivity to industry inputs, ports, and intermodal facilities; challenging terrain, geometric constraints, limited network.
- Measurement: Multi-metric approach used to compare across counties

Network coverage: truck & rail network density.

Area-based, activity: employment w/in 3 hours.

Area-based, network access: drive time to cargo airport, intermodal rail facility.

Conclusions

- Traditional infrastructure-based or network measures address the underlying causes of accessibility issues
- Area-based measures capture the scope/severity of access constraints within a given comparative framework
- Together these metrics serve as important indicators of economic competitiveness
- While there will be continuing advancements in methodologies and available tools, there is sufficient information available within MPOs/DOTs for these measures to be useful now.
